

Disk/File system investigation

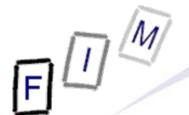

Computer forensics

Institute for Information Processing and Technology (FIM)
Johannes Kepler University Linz, Austria

E-Mail: sonntag@fim.uni-linz.ac.at http://www.fim.uni-linz.ac.at/staff/sonntag.htm

- Acquiring a forensic copy
- Preliminary stages
 - → Image hashing
 - → Partition/file system information
- Removing known files
- Identifying file types
 - → Hash databases
- Creating a timeline

Acquiring a forensic copy: Write blockers

- Never work on the original media
 - → Anything going wrong → The evidence is gone!
 - » Even just a suspicion of that may be enough in a process!
- So we need a copy…
 - → But during copying the media is accessed as well!
 - → Additionally, we don't want a copy of the files ... we want a copy of the whole medium!
 - » This is not the same: Unallocated clusters are e.g. not copied when transferring (all) files through a share
- Result: Create a binary copy of the source media while applying some kind of write-protection to the original
 - → This may be quite easy: Floppy disks/USB sticks do have a "write-protect" "switch"
 - » But can we trust it? And what about media without them, e.g. normal hard disks?

Acquiring a forensic copy: Write blockers

- Therefore we need a separate write blocker
 - → Which is under the control of the person performing the copy!
- Use a trusted hardware write blocker
 - → Exist for all kind of media: IDE, SATA, flash-disks, SCSI, ...
 - » Note: More "exotic" or high-performance → Expensive
 - This is not a mainstream hardware sold in thousands!
- Alternatively use a software write blocker
 - → Problem: Many things can go wrong, e.g. configuring it for the wrong device, bugs etc.
 - → Additionally, it should only be used on a trusted computer
 - » Not: Installing/Running a write-blocker on the source machine
 - You don't know what else is installed there and whether this will actually work or not!
 - → Typical example: USB write blocker
 - → Potential problem: Reboot may be required

Hardware write blockers: How they work

- Two kinds exists
 - → Same interface on both sides: IDE IDE
 - → Different interfaces: SATA USB/Firewire
 - » The typical computer-side is USB and/or Firewire
 - Future: Perhaps eSATA; but not yet available!
 - » Advantage: USB and Firewire are hot-swappable!
- Basic work process
 - → Intercept commands writing to the disk
 - » Problem: Custom extensions!
 - Best approach: Don't allow anything not explicitly know to not modify the data and block everything else
 - Note: This may break compatibility with exotic systems!
 - » Return OK/Failure depending on configuration
 - → Pass all other , i.e. read-only, commands
- See http://www.cftt.nist.gov/hardware_write_block.htm for tested appliances!

Hardware write blockers: Examples

- Examples:
 - → FastBloc
 - » http://www.encase.com/products/ee hardware.aspx
 - → ICS DriveLock
 - » http://www.icsforensic.com/index.cfm/action/catalog.browse/category/DriveLock/id_category/c14d69f1-dcb6-47ab-8be6-1b13217f5b84
 - → WiebeTech Forensic ComboDock v4
 - » http://wiebetech.com/products/ForensicComboDock.php
 - → Tableau
 - » http://tableau.com/index.php?pageid=products&category=forensic_bridges
 - → MyKey NoWrite FPU (owns a patent on write-blocking)
 - » http://www.mykeytech.com/

M

Software write blockers: How they work

- Basic principle: Access the media without passing on write requests; only allow read requests
 - → I.e., on Linux do not mount it in read/write mode, or just "refrain from writing" (USB)
 - » "Not writing" will still change access time
 - » Attention on journaling file systems!
- Not recommended: Setting the USB-write-protection flag in the Windows registry
 - This requires a reboot and is not guaranteed to work!
- In general, SW blockers do the same as Hardware ones
- Comparing Hardware and Software blockers:
 - → SW +: Cheaper and flexible (all devices)
 - → SW -: Platform specific, working not immediately apparent
 - → HW +: Hot-swap, interface conversion, easier to verify
 - → HW -: Expensive, only for selected devices

Software write blockers: Examples

- Digital Intelligence PDBlock
 - → http://www.digitalintelligence.com/software/disoftware/pdblock/
- Linux:
 - → Disable auto-mounting
 - → Mount drive as read-only
 - Example: mount –t <fs-type> –o ro,noexec,noatime,loop <image> <directory>
 - » ro: Do not write to disk, not even for root
 - » noexec: Do not execute files from this disk
 - » noatim: Do not change access time on access
 - » loop: Loopback device, i.e. opening an image as a file system
- See http://www.cftt.nist.gov/software_write_block.htm for test reports of dedicated software!

Duplication issues

- Read errors: What to do when encountering erroneous sectors on the source media
 - → Try to get the data nevertheless (several retries)
 - → If really not accessible, then it wasn't for the suspect as well!
 - » When still suspected → Hardware investigation (platter surface)
 - → Write zeros ('0x00') to the destination instead
 - » This will cause the least harm and not introduce other material
 - » Additionally, mark it as "BAD" externally or within
- Wiped destination disk
 - → Ideally, the destination disk should be wiped before acquiring
 - » This means all zeros, not just a complete formatting!
 - » Reason: Read errors, larger size, ... precaution
 - → Not needed when acquiring to an image file
- Large disks may require multiple destination volumes
 - → Splitting the image into several image files
- Michael Sonntage Care required on analyzing: Seams Imputer forensics: File system investigation

Forensic duplication file formats

- EnCase: "Standard" in law enforcement (".E01")
 - → Proprietary file format, certain metadata
 - → Supports compression
 - » Requires more CPU power to work with, but less space
- Raw: Bit-by-bit copy of the source
 - → Every program can work with this format
 - → There is no compression and no metadata
 - » Compression only for transfer possible, not for working with it!
 - → Integrity check must be external (separate file with hash)
- AFF: Advanced Forensic Format (".AFF", ".AFD")
 - → Open format: Documented, no royalties, BSD-licensed code
 - → Supports arbitrary metadata
 - → Includes metadata, compression, chain-of-custody recording
 » In future should also support encryption
- Several other exist: http://www.forensicswiki.org/wiki/Forensic_file_formats

 Michael Sonntag

 Computer forensics: File system investigation

Creating a forensic duplication: dd

- dd = Data Dump; Used to create binary copies
- Example: dd if=/dev/hdb of=SuspectHD.bin conv=notrunc,noerror,sync bs=1024
 - → if: Input device
 - → of: Output device; just a normal file here
 - → notrunc: Don't truncate output on errors
 - → noerror: Do not stop on read errors
 - → sync: Write zeros on read errors instead of skipping sector
 - → bs: Block size. Default = 512; better performance with larger values, but read errors always affect complete block
 - » Use the physical size if possible; usually 512
 - → count: Number of blocks to copy
 - » Must be multiplied by "bs" value to get bytes!
 - → skip: Number of blocks skipped before copying starts
- Make sure that "of" is mounted, but "if" is not!

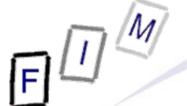

Creating a hash of the whole image

- Important to assure the identity of the image and the source
- Therefore two hashes should theoretically be built
 - → One of the source drive
 - → One of the image
- Actually, usually only a single one is calculated, as reading the source again would not be different from image creation!
 - → Still important: Later modifications of the image can be detected easily
 - → Additionally, in case of doubt, the original can be read and hashed and compared to the image which as analyzed
 - » Helps against swapping images or malicious modifications
- Typically SHA-1, SHA-256 or MD5 is used
 - → MD5 should not be used any more, as it is known to be susceptible to attacks (not yet broken)

Creating a hash of the whole image: Example

- Example for creating a MD5 hash:
 - → chmod 444 SuspectHD.bin
 - → md5sum –b SuspectHD.bin >md5sum.txt
 - → chmod 444 md5sum.txt
- Example for checking:
 - → md5sum –c md5sum.txt
 - » File need not be specified stated in md5sum.txt!
- Content of md5sum.txt:
- → 3be6330d9da0db04d45ef96c86bd7afc SuspectHD.bin See "sha1sum" for calculating SHA-1 hashes
 - → "shasum" calculates other versions as well
 - » Algorithm: 1, 224, 256, 384, 512
- Note: chmod is only there for "security": Read-only files!

Duplication + Hashing: dcfldd

- Slight enhancement of "dd", the disk duplication SW
 - → Open source program
 - → Created by the DoD Computer Forensics Lab (DCFL)
- Features:
 - → Hashing of the data on the fly (=during duplication) » Not only for whole file but also for smaller blocks
 - → Status output (progress bar)
 - → Supports disk wipes with special patterns (not just zeros)
 - → Multiple and split output possible
 - → Produces raw images only

Duplication + Hashing: dcfldd

- Example: dcfldd if=/dev/had of=/mnt/evidence/disk_a.dd conv=sync,noerror hashwindow=1024 hashlog=hash.txt
 - → Parameters similar to dd
 - » if: Input device
 - » of: Output device
 - » sync: Write zeros on read errors instead of skipping sector
 - » noerror: Do not stop on read errors
 - » bs: Block size. Default = 512; better performance with larger values, but read errors always affect complete block
 - Use the physical size if possible; usually 512
 - → Additional parameters (hashing):
 - » hashwindow=1024: Separate hash for every 1024 bytes
 - » hashlog=hash.txt: Where to write the hash values
- Windows:
 - → if=\\.\PhysicalDrive3

Partition and file system information

- "Volume": Careful, it can mean many things!
 - → Collection of addressable sectors
 - » Not necessarily on one physical device or consecutive sectors
 - » Must only look to the OS/application as if it were cons. sectors!
 - → Single accessible storage area within a single file system
 - » Typically within a partition
 - → An entity that has a drive letter mapped to it
 - » Therefore applicable only to Windows, not Unix
- Physical disk organization can be complex.
 - → Several disks can be grouped to create a single "volume"
 - » Example: RAID-0 (Striping)
 - → This volume can then be split in several partitions
 - » Within an partition there can be more partitions
 - → Each partition has a single file system
 - → Not the whole disk must be assigned to partitions

Partition and file system information Forensic considerations

- On complex or uncommon systems, copying the physical disk may not be very useful
 - → String search is always possible
 - » Unless partitions are compressed or encrypted!
 - → But recreating the file systems may be impossible
 - » Depends on the OS used, which may not be available
- Sometimes it may therefore be better to do a "live" copy
 - → Start the system and copy all files to another computer with a "common" file system
 - → Note: All slack space, deleted files etc. are lost!
- Best, but most expensive/time-consuming approach:
 - → Create two full physical copies
 - » One for physical-drive-analysis and an "original" as evidence
 - → Boot from one copy and create a file system duplicate
 - » If possible, use VMWare → Snapshot allows reverting changes!

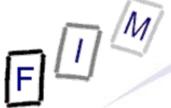

DOS partitions

- The most common type of disk organization
 - → DOS, Windows, Linux, BSD; most multi-boot systems
 - » 32 Bit versions only; 64 Bit versions are often different!
- Basic layout: See file systems!
- A DOS partitioned hard disk can only contain 4 partitions
 - » These are called "primary partitions"
 - → But one can also be an "extended partition"
 - » This can contain several "logical" ("secondary") partitions
 - In theory, only two: A normal and again an extended one, ...
 - → Any of the sub-partitions could be from a different OS and be organized differently within!
 - → One partition may be marked as "active" or "bootable"
 - » This will be the one the system boots from
 - » Note: The code in the MBR record may decide otherwise, perhaps based on user input, or change the markings!

MBR / Partition table example

- MBR = Master Boot Record
 - → 0-445: Boot code (to be executed on booting the system)
 - » 440-443: Windows ≥ NT: NT Drive Serial Number
 - Also used by Linux 2.6 to determine boot volume location
 - → 446-509: Partition table (space for describing 4 partitions)
 - → 510-511: Magic number: 0x55, 0xAA
- Partition table:
 - → 0: Bootable Flag (0x80 = Boot partition)
 - → 1-3: Start CHS address
 - » Cylinder-Head-Sector; Only for old/small hard disks
 - → 4: Partition type
 - » E.g. 0x06 (FAT16, 32MB-2GB, CHS), 0x0c (FAT32 LBA), 0x83 (Linux), 0x84 (Hibernation), 0x86 (NTFS Volume Set), ...
 - → 5-7: Ending CHS address
 - → 8-11: Starting LBA address
- Michael Sonntage 12-15: Size in sectors

MBR example

Boot code

Error messages

NT Drive Serial Number

Partition table

Magic number (Signature ID)

- Text for error messages is at the end of the code
- The three bytes before the serial number are the relative offsets of the individual messages
 - Allows translations of different length without changing the code

parameter block

BIOS

0x054:

0x0B

HPA – Host Protected Area

- Hidden area on the disk invisible to the OS
 - → Introduced with ATA-4 standard
 - → Usage e.g.:
 - » Repair info for OS (copy of installation DVD)
 - » Theft recovery and monitoring services
 - » Reducing capacity of disks to match existing ones
- Properties:
 - → Survives formatting the disk
 - → No access by user, OS or BIOS
 - → Accessible through directly issuing ATA commands
 - » "READ NATIVE MAX ADDRESS (EXT)": Read physical size
 - » "SET MAX ADDRESS (EXT)": Set maximum addressable size
 - → "Volatile" bit: Changes revert on next power up/reboot
 - » Useful for imaging: The disk itself remains unchanged!
 - Careful with write blockers: They may block the necessary ATA commands as they change the disk, although only temporarily!

DCO – Device Configuration Overlay

- Modifications/hidden area invisible to the OS
 - → Reduce disk capacity to exactly match existing ones
 - → Remove special (optional) features of the controller
 - → Introduced with ATA-6 standard
- Properties:
 - → Survives formatting the disk
 - → No access by user, OS or BIOS
 - → Modifications are always permanent
- DCO and HPA can exist on the same disk
 - → First set DCO, then reduce size through HPA!
 - » READ NATIVE MAX ADDRESS will return the reduced size!
 - » DEVICE CONFIGURATION IDENTIFY shows the actual size

HPA + DCO vs. computer forensics

- Both are simple to detect manually:
 - → Read number of sectors from physical drive (Internet, sticker)
 » But label on drive need not necessarily be the original one ...
 - → Compare to information obtained on the computer
- HPA can also be detected through software
 - → Retrieving physical size and comparing it to the maximum addressable sector
- Changing the DCO is always permanent!
 - → No "volatile" bit → Image first, the remove DCO and image all/the rest again. The disk is modified through this!
- Imaging without HPA/DCO will produce incomplete copies
 - → And return different hashes than copies including them!
- Good forensic programs handle HPA (automatically), but DCO seems to be still a problem
 - → This applies to disk wiping programs as well ...

Removing know files

- Usually a disk under investigation will contain an operating system, i.e. several thousands of uninteresting files
 - → But you can't be sure, that everything in "C:\Windows" is from Microsoft and completely unchanged ...
 - → Applies to any other "known" files as well
- Simple approach: Compare file names and contents with installation media and securely downloaded updates
- Better: Create hash values of all files and compare them to public libraries of hash values of known files
 - → These exist for OS, applications, malware etc.
 - → Private libraries also exist for illegal files, e.g. child porn » This is legal: Only the hash value is stored, not the file!
 - → md5deep calculates hash values on numerous files, esp. also recursively (has some other nice features as well)!

M

Hash libraries

- National Software Reference Library
 - → Contains hash values of known and traceable software applications, but none of illegal data
 - → Currently 14.563.184 hash values (1.6.2008)
- Previously: Four CDs
 - → Non-English software, English software (OS), Application software, Images and graphics
- Now: Four CDs
 - → Split according to the SHA-1 hash value) » 00...-3F..., 40...-7F..., 80...-BF..., C0...-FF...
- File format: CSV
 - → SHA-1, MD5, CRC32, Filename, Filesize, Product + OS code
 - → "0000004DA6391F7F5D2F7FCCF36CEBDA60C6EA02", "0E53C14A3E48D94FF596A2824307B492","AA6A7B16", "00br2026.gif",2226,228,"WIN",""
 - » Corel Gallery 750.000, English, Windows

Identifying file types

- Important to identify files intentionally misnamed
 - → Changing the name from "drugs.doc" to "cmd.com"
 - → See also temporary office files: ".doc", ".xls" → ".tmp"
- Also important after undelete or file carving
 - → The filename may no longer be available, but the content is
- How it works:
 - → Most file formats include some kind of header or footer with specific value at certain positions: "Magic numbers"
 - → Linux: "file" command
- Example:
 - → # MS Access database
 - → 4 string Standard\ Jet\ DB Microsoft Access Database
 - → At position 4 the string "Standard Jet DB" is expected
 - → Format: Position Type Value Document-type

"Magic number" examples

Identification example

- Example file: "cmd.com"
 - → Note: Both "command.com" and "cmd.exe" do exist in "C:\Windows\System32" (Windows command line)!
- Output on a Linux machine: [user@host ~]# file cmd.com cmd.com: PDF document, version 1.4
- Suggested actions:
 - Make a copy to a different disk» Keep original disk and file unchanged!
 - → Rename extension to PDF
 - → Open with Acrobat Reader

cmd.com

Creating a timeline

- Timeline: When any/certain actions were taken
 - → Take care: Usually all you get is computer local time!
- May contain various elements
 - → When the computer was started/stopped
 - » Use of company resources outside working hours
 - → When certain files were created/deleted/modified/accessed
 - » Creation: E.g. rootkit installation
 - » Modification: Modification date past the date stated within
 - Example: Backdating letters, modifying balance sheets, ...
 - » Deletion: After notice of proceedings → Evidence destruction
 - → When a certain user was logged in/active

Creating a timeline

- Sources: MAC time of files, log files / Registry
 - → HKLM\System\CurrentControlSet\Control\Windows\Shutdow nTime: 64 Bit Hex datetime value
- Hints:
 - → Compare e.g. web cache files to their timestamps to detect clock skew!
 - → Look for inconsistencies in the naming of System restore points (which are created in increasing numbering and are timestamps, as they are files, directories, etc.)

- MAC = Modification, Access, Creation time
 - → Some file systems have other metadata as well!
 - → Access time is fragile: Most actions on a file will change it!
 - » Usually not: Appearing in a directory list
 - » Should: Open for display, copy (source & destination)
 - → Modification: When the file was written to
- Note: Modifying these values depends on the OS
 - → On most systems changes can be forbidden
 - » HKLM\SYSTEM\CurrentControlSet\Control\FileSystem\NtfsDisa bleLastAccessUpdate → 1 (Claimed to be default in Vista!)
 - » Linux: mount -o noatime
- Windows specialty: Copying files retains M, but sets new C!
 - → Creation after modification:
 A hint that the file was copied here

Created: Mittwoch, 05. Dezember 2007, 12:55:24

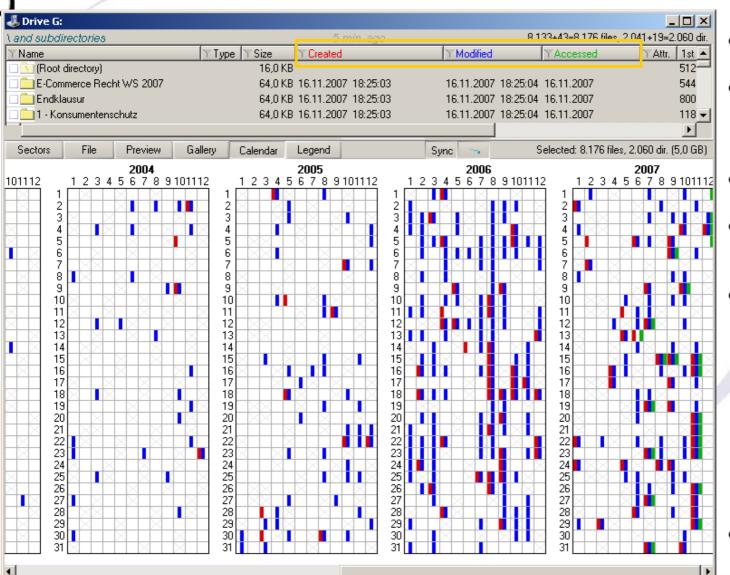

Modified: Mittwoch, 03. Oktober 2007, 12:01:20

Accessed: Mittwoch, 05. Dezember 2007, 12:55:24

→ Not reset on extracting files from an archive!

M

Timeline based on MAC: Example

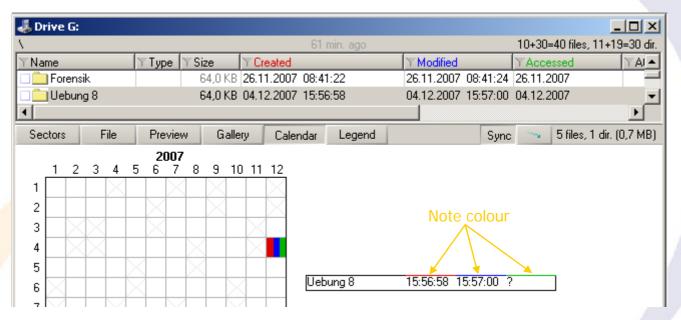

- Access dates only after 13.6.2007
- Creation dates are rather recent, compared to modification dates
- Files must have been copied there
- Older C dates: Probably extracted from ZIP files!
- Notice the "blue line" in 8/2006:
 Continuous work over the weekends!

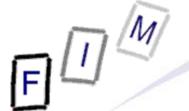

Gray crosses: Weekends!

Timeline based on MAC: Example

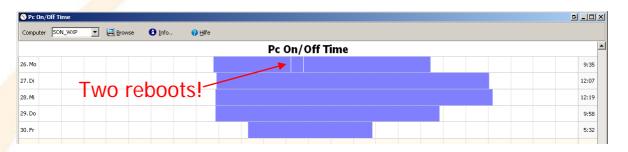

- File information on hovering the mouse
 - → Note: The hovering is not quite correct: The access date is not shown in the popup, although marked in the calendar and shown in the directory view above!

Startup and shutdown information

- Recorded in the system log: Detailed time
 - → When this is cleared, the information is gone!
 - » Traces may remain on disk → partial information

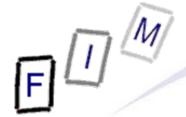

- Based on MAC times of all files and all log entries
 - → Results only in vague times: When the computer was definitely on (single last shutdown time: Registry time)
 - » But it might have been on at other times as well ...
- Manipulating the local clock allows falsifying such data
 - → But this is difficult: All file times must match these values too!
- Linux is similar to Windows: Specific entries/MAC+whole log

Conclusions

- The first and most important aspects of forensic are the Three "P's" of evidence: "preserve, package, protect"
 - → This especially includes using write blockers
- Computer forensics is not only undeleting files
 - → There are many small but important areas as well, e.g.
 - » Partition table examination
 - » E-Mail / Web browser forensics
 - » Recognizing files
 - » Creating timelines
 - » Investigating the Windows registry
 - » Recycle bins, LNK files, ...
- What is therefore needed: Caution
 - → And a good list of where what information might be found, to acquire knowledge/expertise in this area if needed!
